

AMENDMENT

REMARKS

In response to the non-final office action dated 2/24/2005, applicant respectfully submits:

Regarding the rejection of claim 21, element 1 of the claim establishes in detail the process of determining the display status of the displayable data set. The status alone is determined, prior to any visual marking, and furthermore is a necessary step before performing any type of marking. The applicant submits that in the rejection based on Simonson (U.S. Patent No. 6,803,930 B1) col. 4 lines 23-32, col. 5 lines 20-27, and figs. 7, 8, 12a, Simonson makes no reference to determining status of the display, and furthermore does not teach the procedure of determining display status. Applicant respectfully submits that this claim be allowed.

Regarding the rejection of claim 21, element 2, which claims that the process of marking of data is based on a pre-determined display status (as defined in element 1), Simonson does not demonstrate that marking is performed based on pre-determining display status. Determining the display status, or providing the method or algorithm which determines that data which has been displayed and compares it to that data which has not been displayed, is an essential step to the marking process, and must be performed before any visible marking can occur. Applicant respectfully submits that this claim be allowed.

Regarding the rejection of claim 22, which is a system claim of method claim 21, the applicant presents the same discussion as presented above for claim 21, and accordingly respectfully submits that this claim be allowed.

Regarding the rejection of claim 23, element 3 of the claim establishes the process of repeating the process for each subsequent display operation, the rejection is based on Figure 9 of the Simonson patent, however Figure 9 has no specific description or words describing a repetition of the process. Figure 9 has an arrow, however with no associated description of a repetitive process an assumption would have to be drawn to establish that the process automatically repeats. Applicant respectfully submits that this claim be allowed.

Regarding the rejection of claim 25, element 1 of the claim establishes the process of changing spacing between displayed data as a form marking the displayed data.

Simonson makes no reference to changing spacing between displayed data, and furthermore does not teach the procedure of changing spacing. Applicant respectfully submits that this claim be allowed.

Regarding the rejection of claim 28, the claim establishes the process of converting marked data (from the determining status and marking process) to selected data, which may be used in a word processing system. Simonson makes no reference to converting marked data to selected data, in terms of its use in a word processing system, and furthermore does not teach the procedure of converting marked data to selected data for use in a word processing system. Applicant respectfully submits that the use of the word "selected", in the rejection of this claim applies to the verb form of the word, as in the "selection of options". Whereas the claim presents the word "selected" in the form of an adjective which is used to describe selected data, as is known in the techniques used in word processing. Applicant respectfully submits that this claim be allowed.

Regarding the rejection of claim 30, which is a system claim of method claim 23, the applicant presents the same discussion as presented above for claim 23, and accordingly respectfully submits that this claim be allowed.

Regarding the rejection of claim 32, which is a system claim of method claim 25, the applicant presents the same discussion as presented above for claim 25, and accordingly respectfully submits that this claim be allowed.

Regarding the rejection of claim 35, which is a system claim of method claim 28, the applicant presents the same discussion as presented above for claim 28, and accordingly respectfully submits that this claim be allowed.

Regarding the rejection of claims 21-36 and 41-44 based on a reference to a single patent (Simonson U.S. Patent No. 6,803,930 B1) applicant respectfully submits that this reference be eliminated due to the fact that proof of conception was filed in the original application, which swears behind the application date of the referenced patent. The application references a disclosure document filed in the USPTO disclosure document program, which was written and filed before the application date of the referenced patent. The application references the disclosure document (A Method for Displaying and Scrolling Data, Document No. 453185) by a letter of reference included in the application papers, and directly on page 1 of the application in Cross Reference to Related Applications. The disclosure document was mailed on 3/13/99 and registered at the PTO on 3/18/99, while the referenced patent was applied for on 12/16/99. Furthermore the disclosure document establishes the critical concepts of the invention and clearly discloses methods to “visually mark or shade previously

displayed data, so as to differentiate said data from previously undisplayed data”, and supports the claims of the current application.

Applicant respectfully submits that the original patent application which directly references the stated disclosure document, along with the oath and declaration, and disclosure document as held by the PTO in the document disclosure program, meets the requirements to swear behind the date on the disclosure document, in order to satisfy 37 CFR 1.131 .

In addition an affidavit of the same follows;

I, Edwin G. Watson hereby declare that the disclosure document entitled “A Method for Displaying and Scrolling Data”, was mailed to the USPTO on 3/13/99, and filed as Document No. 453185 by the USPTO on 3/18/99, and was referenced directly in the patent application No: 09/804,385. Attachment A of this amendment is a photocopy of the above listed disclosure as mailed, along with a date stamped receipt from the USPTO indicating the document number as filed.

CONCLUSION

The applicant believes that the Examiner will now find the claims of this application allowable. Favorable reconsideration of the application is courteously requested.

Respectfully Submitted,

A handwritten signature in black ink, appearing to read 'Edwin G. Watson', written over a horizontal line.

Edwin G. Watson

Introduction:

This invention disclosure relates to a system and method to display portions of a data set on a viewable device, as typically found in a computer system, and includes methods to discern between data which has previously been displayed as compared to new or previously undisplayed data. More particularly, this invention describes a system and methods which provides scrolling tools which allow a user to view portions of a set of data by scrolling or jumping through the data set while having subsets of the data set displayed in a viewable area of the display system. Furthermore in the process of moving around, and displaying portions of the data set, indicators are shown which alert the operator of those portions of the data set which have been viewed previously.

Background:

A typical computer system and the like consists of a display device which has a function to display data which may reside inside the memory of the computer. Typically the selected data in memory or data buffer to be displayed is larger than the specified display area within the one or more viewable areas of the display device is capable of displaying. As a result a system is required to allow the user to access various portions of the data buffer, as the user sees fit.

Well known to the art is the application of scroll bars which act as the graphical interface in which the user can direct the system to display the desired portion of the data buffer in visible area of the display by employing a point and click device, such as a mouse. Said scroll bars typically are arraigned in a vertical and horizontal fashion, providing vertical and horizontal control respectively. Functionality of the scroll bars include gross or fine movements of the data from the data buffer to the display area. Depending on the section of the scroll bar pointed to and clicked on, the scrolling function can be an incremental line by line movement of fresh previously undisplayed data to the display, or page by page movement of fresh data to the display, where a page is considered substantially the amount of data in the display area. The scrolling motion can be, but is not limited to, a forward or backward direction relative to the data buffer, and a vertical or horizontal direction. The scroll bar typically consists of a multifunctional slider block of which one function is to show the position of the viewed data with respect to the whole of the data in the buffer by the visible position of the slider block in the scroll bar. A second function of the slider block is to show the relative size of the viewed data to the whole buffer size, by displaying an adjusted size of the slider block within the scroll bar. A third function of the slider block is to be grabbed by the pointer device and slid along the slider bar thus displaying portions of the data buffer in proportion to the relative position of the slider within the scroll bar. Scrolling page by page, or jump scrolling is typically accomplished by a single click of the pointing device in the area of the scroll bar adjacent to the slider block on the side of the slider block pertaining to the direction that the user wishes to scroll. When scrolling page by page the system determines what the current size of the viewable area is

an acquires from the data buffer a substantially equal amount of fresh data adjacent to the displayed data, and displays that data to the display area, displacing the currently viewed data and thus providing a contiguous feed of data to the display. In the previous procedure, when the end of the data buffer is approached, in any direction, the last block of fresh data is typically smaller than the visible area of the display, resulting in the visible area of the display being only partially filled by fresh data after a page by page scroll event. The user while viewing the data usually can expect fresh data to be displayed at the top of the viewable area, whereas the fresh data, if smaller than the visible display area, will begin somewhere in the middle of the display area. resulting in an interruption in the users continuous viewing of the data.

This invention therefore proposes a system and methods which allow a continuous presentation of data while scrolling through data, by any means or direction, which allows the user to see fresh, previously undisplayed data, with respect to previously displayed data for any size data buffer or viewable display area. The system consists of means to determine sizes of the data buffer in memory, size of the current display area or areas, position of the currently displayed data with respect to the data buffer in memory, and to mark data which has been displayed, so as to arrange new data to be always be displayed in the expected portion of the display area, or visibly mark or shade the previously displayed data, so as to differentiate said data from the fresh previously undisplayed data. Multiple differentiator means may also be implemented which distinguish data which was last to be displayed from second, third, or more previously displayed data events, in a time history fashion. Differentiation means may also be implemented which distinguishes data which has previously been displayed and is forwardly placed in the buffer versus afterwordly placed, with respect to the currently buffer position, and relative to the direction of motion through the data buffer.

Summary:

The disclosed invention comprises a system and methods for providing scrolling of data in a typical computer system and the like. The scrolling system includes, but is not limited to a data buffer or data storage or memory area which stores data to be displayed on a display device and presented to the user, and can be controlled by the user. Said data may be, but is not limited to, incoming data from any type of connection to other systems, data which is stored within the computer, or data which is the result of some application or calculation. Said data may be of any type or format, including but not limited to text, graphics, or a combination thereof. A display device having one or multiple viewable display areas which may be addressed individually or simultaneously, at the discretion of the user. Said viewable display areas with one or multiple scrolling means to control the movement of data from said data buffer to said visible display area. Said scrolling means preferably consisting of scroll bars, slider blocks, and one or more directional arrows, which provide an interface means for the user to direct the scrolling system how and where to move the visible display through the data buffer. A point click device such as a mouse for providing a means for the user to address the functions of said scroll bar and its

elements. The designated currently displayed data set, being a subset of said data buffer. The designated currently undisplayed data, being a subset of said data buffer, and being that subset which is substantially that not being a part of said currently displayed data. The designated set, never displayed data, being a subset of said data buffer, and being a subset of said currently undisplayed data and being identified as not being previously displayed within a given time period or designated viewing session.

In addition the disclosed invention may incorporate an algorithm by which the status of the display is compared to the input by the user for a display change, and whereby the subsets of data are compared for status of being displayed, resulting in a display of data as the user requested, and presented in a fashion which allows continuous presentation of the data to the user, along with markers which identify status and or display history of said data as necessary. Methods to mark or discriminate said displayed data and the status thereof, for example but not limited to, the background shading or gradient shading of said data which may have been just previously been displayed as a result of the last scroll input command, so as to identify to the user that said data was available for viewing in the previous configuration of the display area, and may have already been viewed by the user, whereas the non shaded data is freshly retrieved data and typically the user can direct their eyes to that area of the display for resumption of viewing. Other means not specifically mentioned can also be employed to achieve the same differentiation means and are within the spirit of the invention, including but not limited to bold lettering, underlining, font changes, spacing changes, etc.

The display of a small portion of just previously displayed data in a new configuration of a view area is sometimes advantageous for continuity of display, however identifying said data as such is further helpful in resuming viewing data and such. The display a some portion of just previously displayed data in a new configuration of a view area is sometimes unavoidable because when approaching the limit of fresh data in said data buffer. Said fresh data may require a smaller display area than the current display area is sized to, and as such may not displace a significant portion of the just previously data, resulting in the fresh data being displayed at an unexpected location of the viewable area in combination with a significant amount of just previously displayed data. This phenomena results in the user having to scan to field to locate the beginning of the new data field. The disclosed system thereby marks and distinguishes the just previously displayed data from the fresh data and allows the user's eye to quickly locate said fresh data, and resume viewing.

In another embodiment of the disclosed invention, said system algorithm means always locates the start of fresh data to a predetermined location in the viewable area, regardless of the relative size of the fresh data as compared to the viewable area data size, and regardless if the end of buffer is reached. Said algorithm means may also fill void areas with null data, added to the buffer or view data, to accommodate filling the viewable area. Shading or other identification means may be used in conjunction with said repeat location method to further identify new and/or old data.

In another embodiment of the disclosed invention, the system identifies or relocates data in the viewable display area when said viewable display area is changed by resizing, or stretching or the like. Identification of said data is similar to said methods of determining

Signature and Date: E. J. Watson 3/13/99

fresh from previously displayed data, as detailed above. relocation of data is similar to that described above whereby fresh data is routinely located on one predetermined portion of the viewable area. Yet another embodiment incorporates an algorithm means which resizes the viewable area to adjust to incoming buffer data which may be less than that amount needed to substantially fill the viewable area.

Figure (1) depicts one embodiment of the disclosed invention, showing relations between said data buffer 1 and viewable display areas 2-4, 16 and 19 at various locations in the travel through said data buffer 1. As a user may travel from top to bottom of data buffer 1, a viewable display area 2 is shown as it would display a portion of data buffer 6, which is substantially in the middle of data buffer 1, and is identified by an algorithm as the currently displayed data 6, and in this particular case as never before displayed data, and is displayed as such on the display 10. Scroll bars and controls 15a preferably are employed by the user to invoke moving said data buffer 1 through said display area 2, and in this operational example where said data buffer 1 was originally accessed from the top, prior to displaying the currently displayed data 6, having earlier displayed a set designated previously displayed data 5. Similarly data in said buffer 7, having never been displayed is designated by the algorithm as never displayed data. As a user may travel toward the end of said buffer 1, to a currently displayed data set 8, which displays on a display area 3 as displayed data 11, all areas at this time in the course of events that were previously displayed are designated as previously displayed data. From this given position in said data buffer, as the user may choose to initiate a scroll down in the display area 3, using controls 15b, whereas the remaining data in said data buffer 1, currently designated as never displayed data 9 requires by nature of display area parameters, less display area than the display area currently offers, the scroll action results in a display area 4 with said never displayed data 9 being displayed in area 12, and previously current and now previously displayed data 8 being displayed in display area 4 with a means of marking, shading, or otherwise differentiated displayed data 13. Said differentiating means allows easy and accurate continuation of viewing by the user whereas the new data 12 is not displayed with a starting location as expected by the user, as may have been the norm for previous scroll events.

A particular display area 16 shows currently displayed data 17 and previously displayed data 18 which may occur in the event the user using scrolling means, scrolls backward from a fully current display 10 to redisplay data designated as previously displayed data 5. In a different embodiment, a display area 19 incorporates an algorithm which when determining that the requested previously undisplayed data 9 requires less area than the display area 19 offers, displays the previously undisplayed data 9 at substantially the expected position in the display area, and further generates and displays null or fill data 21 to fill the remainder of the area.
